
AquaSave

…Jane Doe is in a happy mood

Does she notice the unused water flowing from the tap?

Perhaps she can’t fathom the potential of that water?

Let us make these litres of water sound like something she can easily relate to!

AquaSave

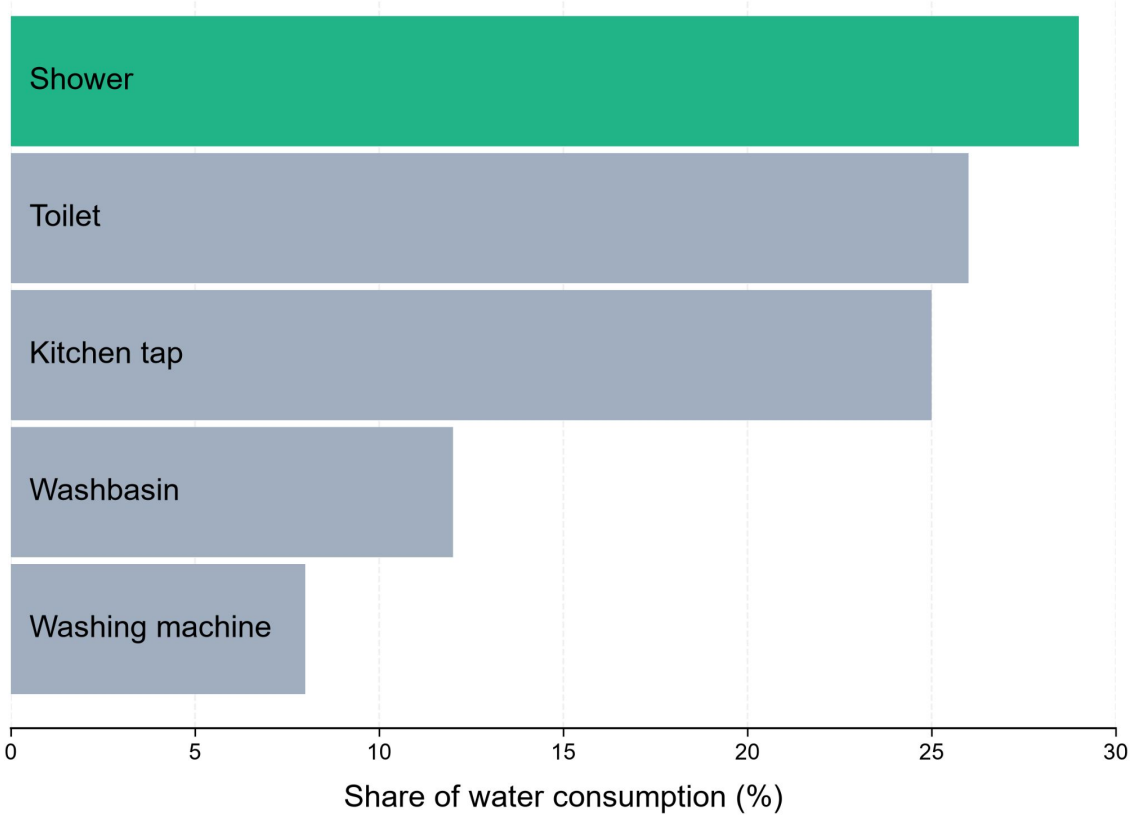

…data points out events with the highest water consumption

Showers* accounted for

29%

of the total water consumed.

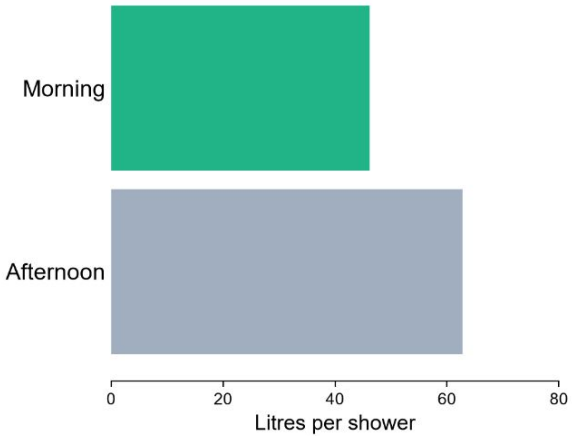

*Showers recorded include **private** and **shared bathrooms**

AquaSave

…water consumption during showers are influenced by many factors

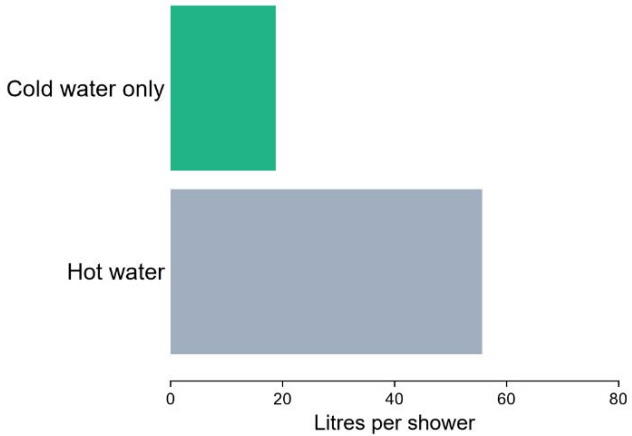

Time of the day

26%

less water in the morning

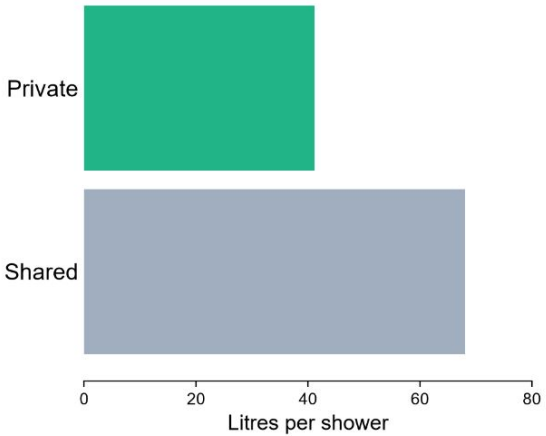

Water temperature

66%

less water during cold showers

Bathroom type

40%

less water in private bathrooms

…AquaSave characterizes efficient showers by three* optimizable parameters

AquaSave Scenario

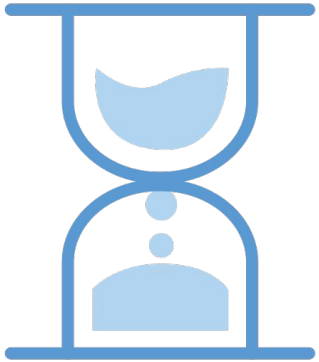

Flow rate = **7.5 l/min**

Litres per shower = **45 l**

Shower duration = **6 min**

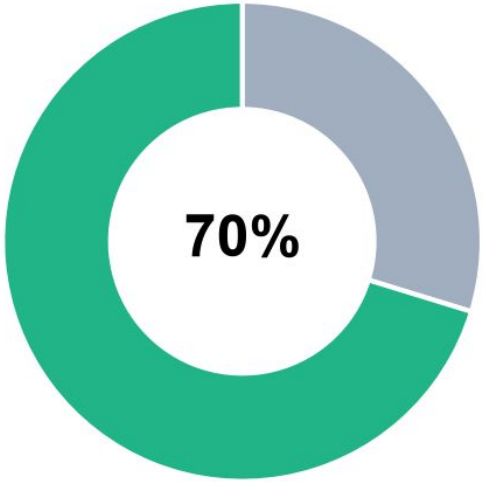

*These values are backed by literature focusing on shower patterns in Germany

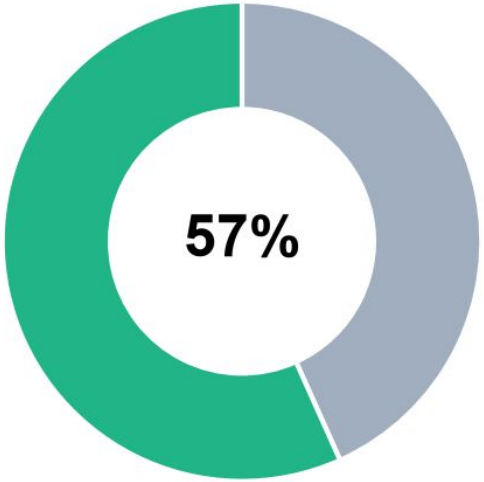

…showers above the AquaSave thresholds account to 80% of water consumption

AquaSave Scenario

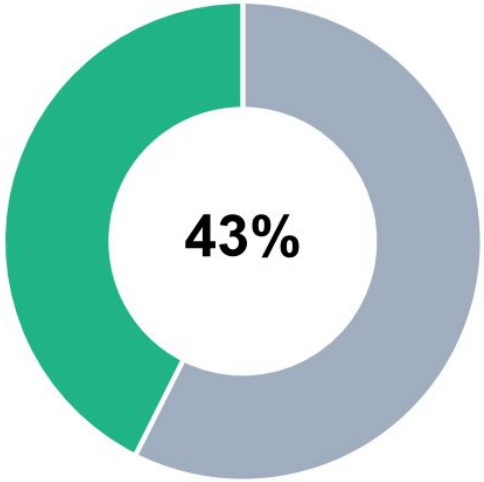

Flow rate < **7.5 l/min**

Litres per shower < **45 l**

Shower duration < **6 min**

Let us calculate your potential water savings with you!

Which topics resonate best with you? Pick 1

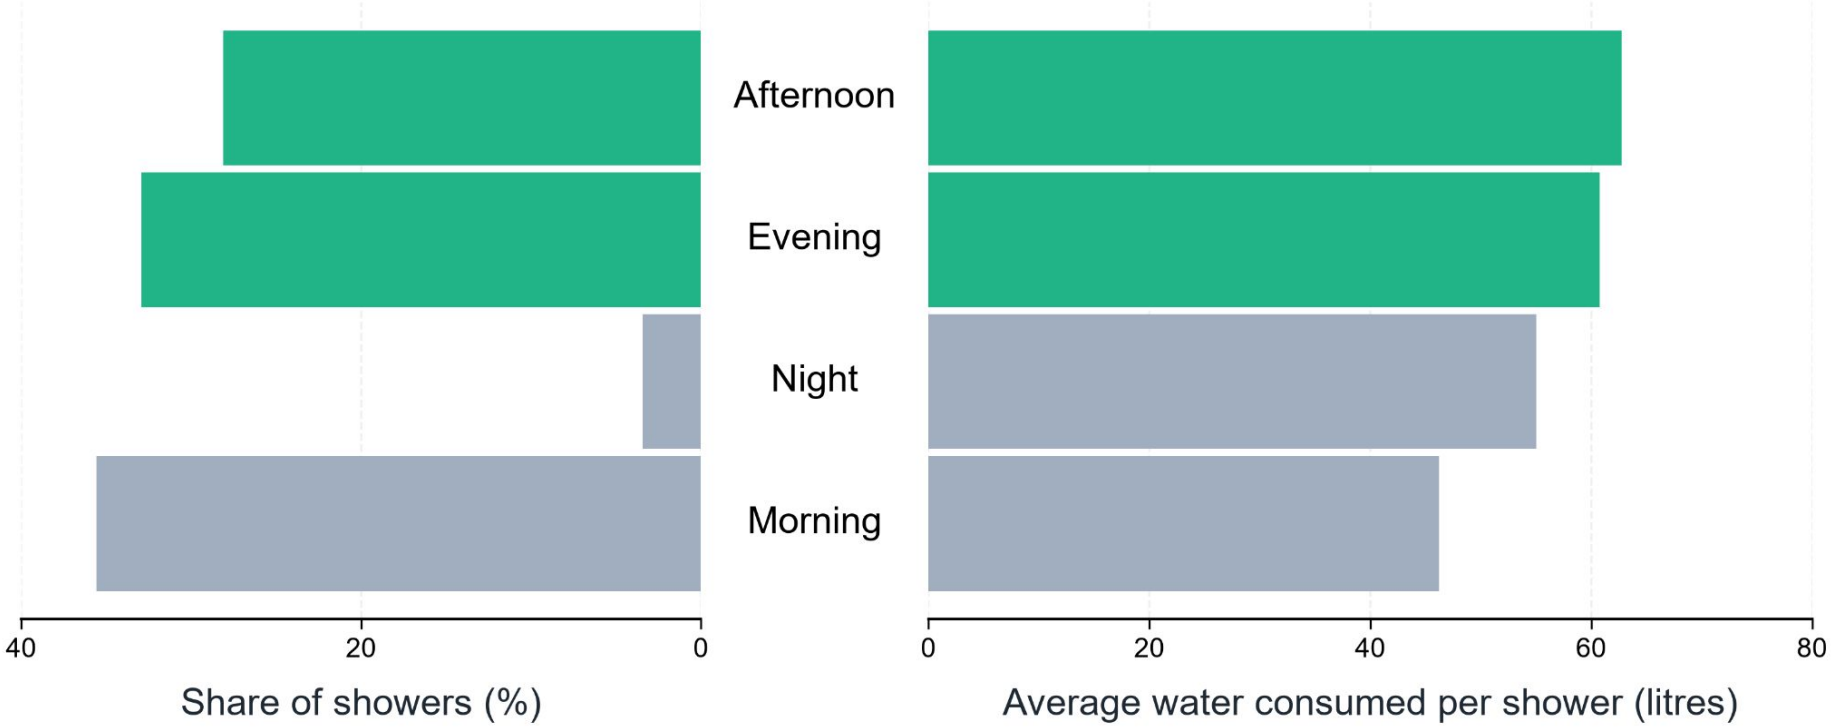

to shower details

Does illustrating your potential water savings in terms of trading something you love, make the concept of **water conservation** more **concrete**?

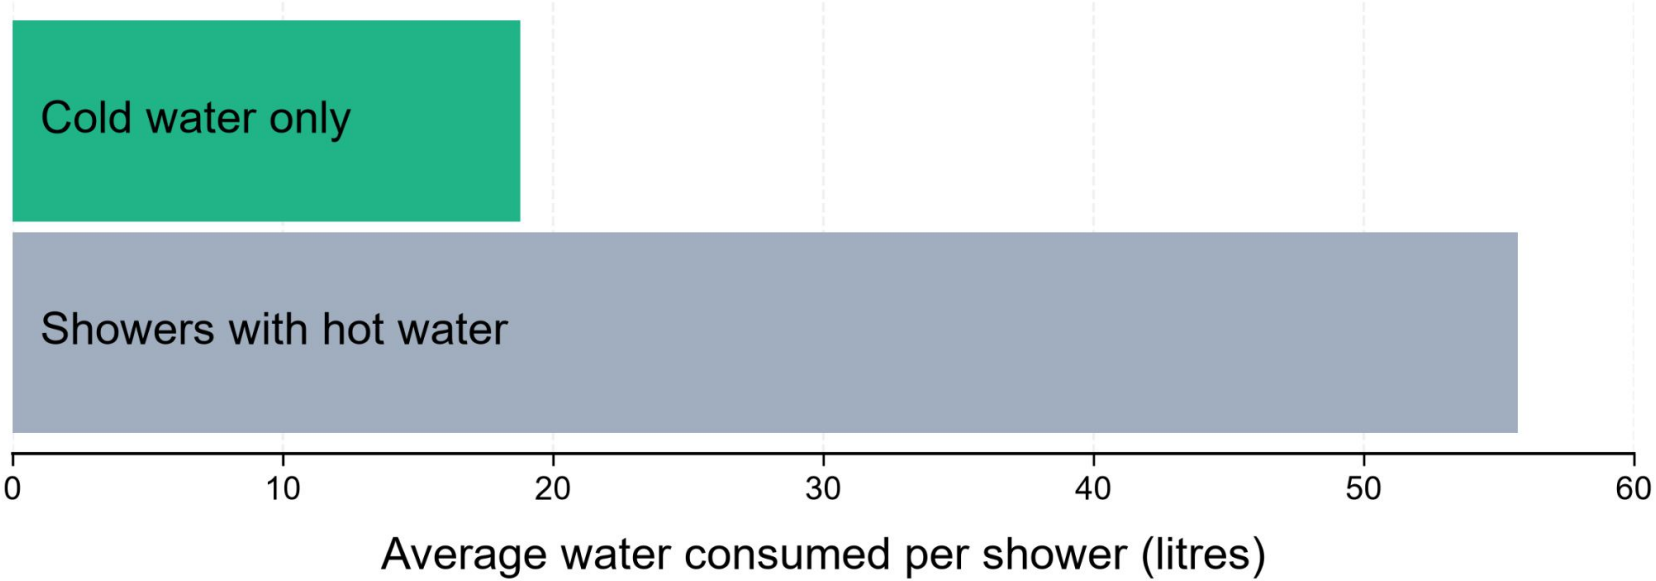

Extra Slides

…more but less intense showers are observed in the morning

Behavioural patterns are evident in water consumption for showers

…water temperature does not have a significant influence on shower durations but water consumed

Cold showers are on average only 1 minute shorter than warm ones

…51% savings are achieved under the AquaSave Scenario

AquaSave Scenario

Flow rate = **7.5 l/min**

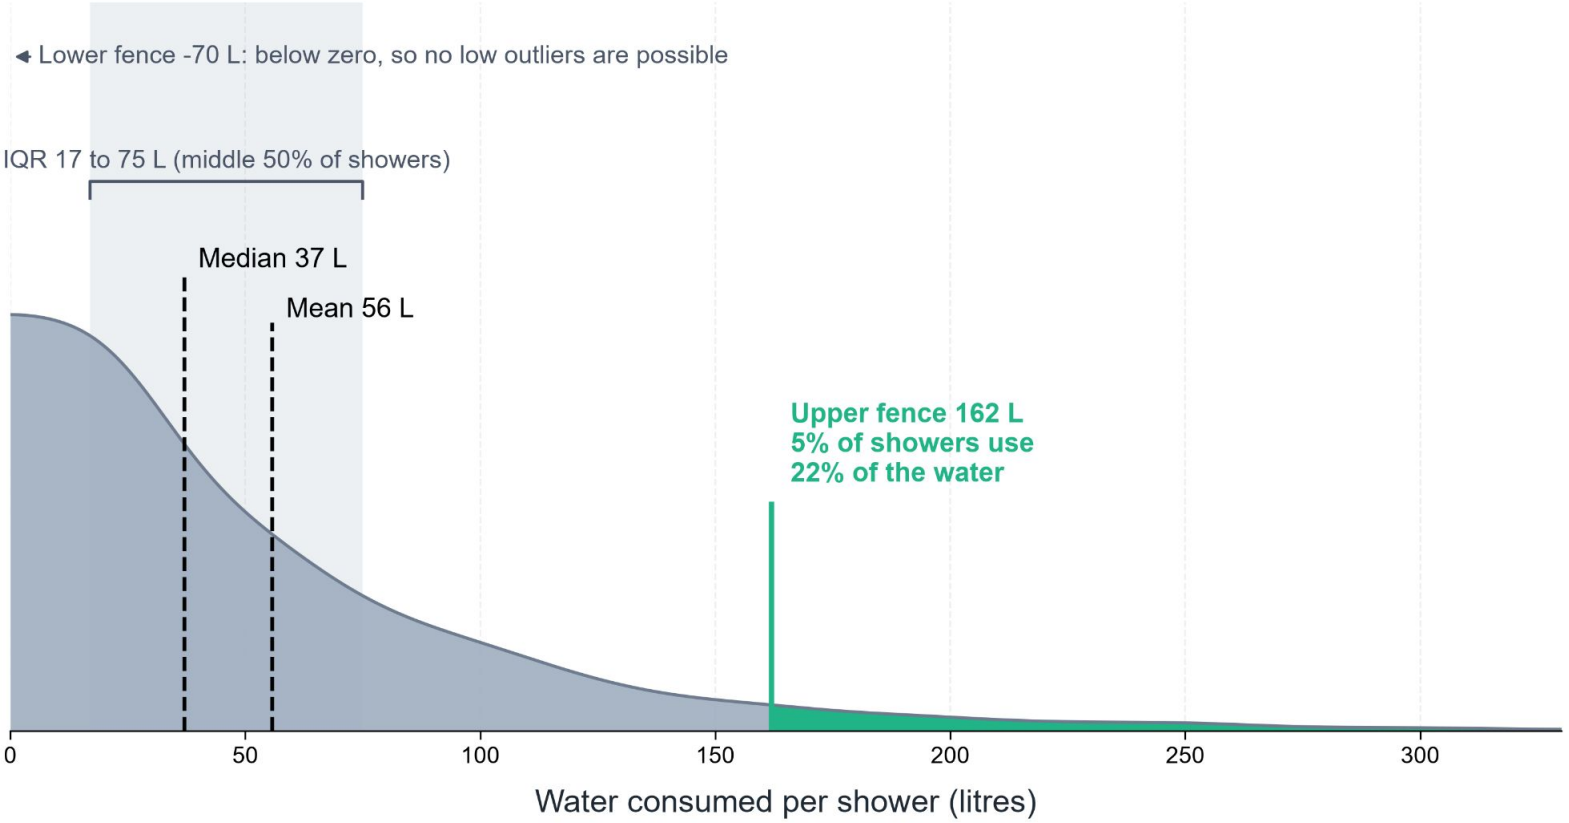

Litres per shower = **45 l**

Shower duration = **6 min**

25% **44%** **46%**

!!! These numbers are **ABSTRACT** and **DO NOT** illustrate something you love!!

…the data is skewed to the right and it is difficult to define outliers

…this concept comes with a lot of limitations

- ➔ There is no certainty that people relate to missing out something they love (e.g. in comparison to monetary comparison)
- ➔ The AquaSave scenario is very inflexible and is detached from non-numerical variables e.g. social household properties
- ➔ The data utilised is strictly numeric without context and has limited flexibility since readings are in 10 minutes resolution
- ➔ One requires some knowledge a regular household resident may not keep track of (flow rate, shower duration, water cap)

…potential for AquaSave

- ➔ Incorporation with billing data and different providers to add a concept of money savings (tends to have a higher motivation)
- ➔ Shower events can be classified using ML to increase accuracy of the predicted water consumption (rather relying on statistical properties)
- ➔ Data from defined household profiles could help enhance the analysis of the data (micro resolution)
- ➔ Validation from water experts and users could help enhance the methodology applied
